

# Competition between $T=1$ and $T=0$ pairing in $pf$ shell nuclei with $N = Z^\dagger$

H. Sagawa,<sup>\*1,\*2</sup> Y. Tanimura,<sup>\*3</sup> and K. Hagino<sup>\*3</sup>

The role of the neutron-proton isoscalar spin-triplet ( $T=0, S=1$ ) pairing interaction in finite nuclei has been a topic of discussion for long.<sup>1-3)</sup> The isoscalar spin-triplet pairing interaction is known to be stronger than the isovector spin-singlet ( $T=1, S=0$ ) one in nuclear matter.<sup>4)</sup> Nevertheless, nuclei favor the spin-singlet  $T=1$  pairing between identical particles. A straightforward explanation for this contradiction is that most stable nuclei have different numbers of neutrons and protons; thus, protons and neutrons occupy different single-particle orbits near the Fermi surface, which leads to the inhibition of  $T=0$  pairing. It was also suggested that the nuclear spin-orbit field largely suppresses the spin-triplet pairing, much more than the spin-singlet pairing.<sup>5,6)</sup>

To clarify the role of  $T = 0$  pairing, we diagonalize the Hamiltonian with the spin-singlet and spin-triplet pairing terms in  $pf$  shell model configurations for nuclei with the same number of protons and neutrons,  $N = Z$ . The pairing correlation energies of the ( $J^\pi = 0^+, T=1$ ) and ( $J = 1^+, T=0$ ) states are shown in Fig. 1 as a function of the scaling factor  $f$  for the  $T = 0$  pairing. The lowest energy state with  $J^\pi=0^+$  for the  $l = 3$  case acquires more binding energy than the  $J^\pi=1^+$  state for the strength factor  $f < 1.5$ . In the case of strong  $T=0$  pairing, that is,  $f \geq 1.6$ , the  $J^\pi=1^+$  state acquires more binding energy than the lowest  $J^\pi=0^+$  state. These results are largely attributed to the quenching of the  $T=0$  pairing matrix element by the transformation coefficient corresponding to a change of the scheme from the  $jj$  coupling to  $LS$  coupling. This quenching never happens for the  $T=1$  pairing matrix element, since the mapping of the two-particle wave function between the two coupling schemes is simply implemented by a factor  $\sqrt{j+1/2}$ . For the  $l = 1$  case, there is a competition between the  $J^\pi=0^+$  and the  $J^\pi=1^+$  states as seen in Fig. 1. Because of smaller spin-orbit splitting in this case, the couplings among the available configurations are rather strong, and the lowest  $J^\pi=1^+$  state acquires more binding energy than the  $J^\pi=0^+$  state when  $f \geq 1.4$ . These results are consistent with the spins observed for  $N = Z$  odd-odd nuclei in the  $pf$  shell, where all the ground states have the spin-parity  $J^\pi = 0^+$ , except for  $^{58}_{29}\text{Cu}$ . The ground state of  $^{58}_{29}\text{Cu}$  has  $J^\pi = 1^+$ , because the odd proton and odd neutron

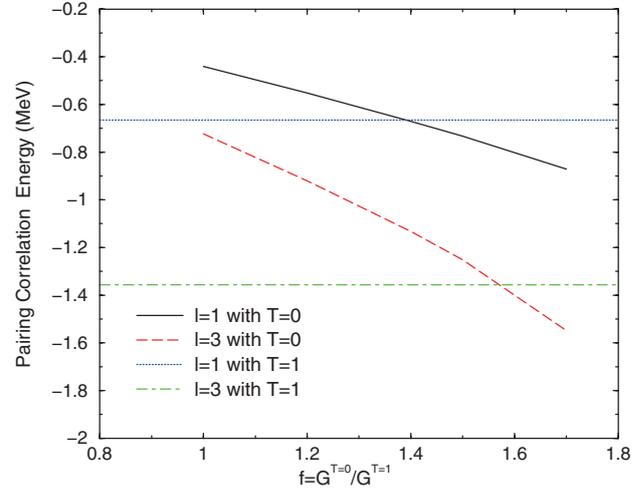

Fig. 1. (Color online) Pairing correlation energies for the lowest ( $J^\pi = 0^+, T=1$ ) and ( $J = 1^+, T=0$ ) states with the  $l = 3$  and  $l = 1$  configurations as a function of the scaling factor  $f$  of the  $T = 0$  pairing. The strength of the spin-singlet  $T=1$  pairing interaction is fixed at  $G^{(T=1)}=24/A$  MeV with mass  $A=56$ , while the strength for the spin-triplet  $T=0$  pairing interaction,  $G^{(T=0)}$ , is varied with the factor  $f$  multiplied by  $G^{(T=1)}$ .

occupy mainly the  $2p$  orbits, wherein the spin-orbit splitting is expected to be much smaller than in  $1f$  orbits.

In summary, by diagonalizing the pairing Hamiltonian, we have shown that the spin-triplet pairing correlation energy in the  $1f$  shell configuration becomes larger than the spin-singlet pairing energy when the strength of the spin-triplet pairing is larger than that of the spin-singlet pairing by a factor of 1.6 or more. However, for the  $2p$  configuration, the spin-triplet pairing correlation becomes dominant even when the factor  $f$  is approximately 1.4.
