Porous crystals of zeolites make it possible to generate periodically arrayed alkali-metal nanoclusters. Various kinds of magnetically ordered states have been observed in these systems, although they do not contain any magnetic elements. Sodalite is a kind of aluminosilicate zeolites where the β cages with an inner diameter of 7 Å are arrayed in a bcc structure as shown in Fig. 1 (a). The chemical formula is given by $A_3\text{Al}_5\text{Si}_5\text{O}_{12}$ per β cage where $A$ indicates an alkali cation. By the loading of guest alkali atoms into dehydrated sodalite, an $A_3^{+}$ cluster is formed in the β cage as schematically shown in Fig. 1 (b), where an s-electron is shared by four $A^+$ ions and is confined in the cage. When Na$3^{+}$ clusters are formed in all the β cages, antiferromagnetic (AFM) ordering occurs below the Neél temperature of $T_N = 48\text{K}^{1-3}$ because of the exchange coupling between the adjacent clusters. The material is assigned to a Mott insulator. When heavier alkali cations are substituted for Na$^+$, $T_N$ systematically increases: 72, 80, and 90-100 K for clusters with average chemical compositions of $K_3^{+}$, (K$_3$Rb)$3^{+}$, and (K$_1.5$Rb$_{2.5}$)$3^{+}$, respectively.4,5 However, a recent work has revealed that Rb$3^{+}$ does not show AFM ordering and shows metallic behavior. In the present work, we investigate in detail the magnetic properties of this system in the vicinity of the insulator-to-metal (I-M) transition by utilizing μSR. The experiments were performed at the RIKEN-RAL Muon Facility using the CHRONUS spectrometer.

Figure 2 (a) shows the zero-field μSR spectra of K-Rb alloy clusters ((K$_1$Rb$_{2.3}$)$3^{+}$). At 5 K, a muon-spin precession signal with a large amplitude is clearly observed. This result indicates that the AFM order is robust in the major volume of the sample even just before the I-M transition. The internal field at the muon site is estimated to be 166 Oe. This is stronger than that in Na$3^{+}$ (92 Oe)9, K$_3^{+}$ (142 Oe), and (K$_1.5$Rb$_{2.5}$)$3^{+}$ (155 Oe)9. A systematic increase in the size of the s-electron wave function in the heavier alkali metals, which is the origin of the enhancement of AFM exchange interaction, is expected to provide a stronger Fermi contact between muon and s-electron. $T_N$ is estimated to be ≥ 90 K from the temperature dependence of the internal field. In contrast, the pure Rb clusters (Rb$3^{+}$) only show very slow relaxation even at 2 K as shown in Fig. 2 (b). This result confirms that a non-magnetic state is realized in the metallic phase after the I-M transition.

Fig. 1. Schematic illustrations of (a) the crystal structure of sodalite and (b) the $A_3^{+}$ cluster formed in the β cage, where $A$ indicates an alkali element.

Fig. 2. Zero-field μSR spectra of (a) K-Rb alloy clusters and (b) Rb clusters in sodalite.
