Study of neutron-rich  $_{54}\text{Xe}$  isotopes with  $N > 82$  is very important for understanding shape evolution from spherical to prolate shapes for nuclei in the mass region beyond the doubly-magic  $^{132}\text{Sn}$  nucleus. In particular, the  $N=88$  nucleus of  $^{142}\text{Xe}$  is expected to have octupole collectivity in low spin region, because the  $^{144}\text{Ba}$  nucleus ( $N=88$ ) is well known for having the large octupole deformation<sup>1</sup>. In this work, to reveal various nuclear structures of  $^{142}\text{Xe}$ , the low-spin states in  $^{142}\text{Xe}$  were investigated using  $\beta$ -decay spectroscopy of  $^{142}\text{I}$  ( $Z=53$ ).

Neutron-rich  $^{142}\text{I}$  was produced by in-flight fission of a  $^{238}\text{U}$  beam at the RI Beam Factory (RIBF) in RIKEN. Particle identification for the fission fragments was performed based on the TOF- $B\rho$ - $\Delta E$  method using the BigRIPS and the ZeroDegree spectrometer<sup>2</sup>. Nuclei were implanted in the 5 double-sided Si-strip detectors (WAS3ABi<sup>3</sup>) at F11. Beta rays and  $\gamma$  rays were measured using the WAS3ABi and the EURICA array consisting of 12 Cluster-type Ge detectors<sup>3</sup>, respectively. In order to measure the half-life of the excited states in the time range from a few hundred picoseconds to a few nanoseconds, a fast timing detector system, which consists of 18 LaBr<sub>3</sub> detectors for  $\gamma$  rays and 2 plastic scintillators for  $\beta$  rays, was installed<sup>4</sup>.

Figure 1 shows the decay curve obtained by the time difference between the implantation of  $^{142}\text{I}$  and the detection of  $\beta$  rays in WAS3ABi gated on the known 287-keV  $\gamma$  rays ( $2^+ \rightarrow 0^+$ ) of  $^{142}\text{Xe}$ <sup>5</sup>. The half-life of the  $\beta$  decay of  $^{142}\text{I}$  was determined to be 229(3) ms, which

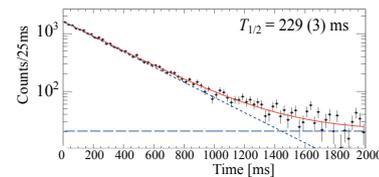

Fig. 1. Decay curve of the  $\beta$  decay gated on the 287-keV  $\gamma$  ray in  $^{142}\text{Xe}$ .

was more accurate than the value of 222(12) ms in Ref. 6. Figure 2 shows the energy spectrum of  $\gamma$ -rays emitted after the  $\beta$  decay of  $^{142}\text{I}$ . Three known transitions in  $^{142}\text{Xe}$  are clearly observed with energies of 287, 403, and 971 keV. The  $B(E2)$  value of 0.6(3)  $e^2b^2$  determined from the half-life of the  $2^+_1$  state, which was obtained as 0.22(9) ns by using the fast timing system, is in good agreement with the one obtained by Coulomb-excitation measurement of 0.7(1)  $e^2b^2$  in Ref. 7. The deformation parameter  $\beta_2$  was deduced to be 0.16(3) using the  $B(E2)$  value in this work. This indicates that the nucleus  $^{142}\text{Xe}$  has a small prolate shape. The decay scheme after the  $\beta$  decay of  $^{142}\text{I}$  was newly constructed in this work with 36 levels up to an excitation energy of 3.2 MeV. Two levels in this new decay scheme were assigned as candidates of the ( $1^-$ ) and ( $3^-$ ) states which are members of the  $K=0^-$  octupole band, populated in high spin region by the spontaneous fission of  $^{248}\text{Cm}$  in Ref. 5. A detailed analysis is in progress.

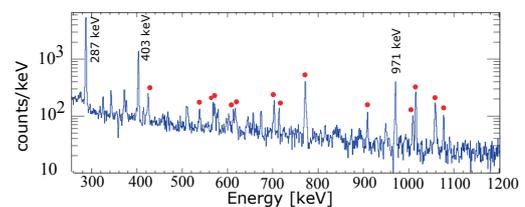

Fig. 2. Energy spectrum of  $\gamma$ -rays emitted after the  $\beta$  decay of  $^{142}\text{I}$ . Peaks with closed circles indicate newly observed  $\gamma$  rays in  $^{142}\text{Xe}$ .
